Coffee Future Price Pediction Project: ICFFUT B3 Dataset

HarvardX - PH125.9x Data Science: Capstone Course

Mauricio Rabelo Soares

03 set 2022

Introduction

A Machine Learning for Factor Investing is a equity **investment strategies** that are built on **firm characteristics**, the goal of this approach is to determine the model that maps the time-t characteristics of firms to their future performance (Coqueret and Guida 2020).[1] Its premise is that differences in the returns of firms can be explained by the characteristics of these firms. In this project we use a similar approach but, instead a firm performance, our outcome is the trade decision taken at close call of 4/5 Arabica Coffee Futures contract traded at B3, which ticker is ICF.[2] The goal of this project is to create a decision trade system which balanced accuracy, or F1 score, is above 50%, [3]using all the tools we have learn throughout the multi-part course in HarvardX's Data Science Professional Certificate series. For this challenge we going to use a dataset provided by the Profit Trader Clear[4]. The dataset begin in January 2003 and has **4435 decisions** applied to **1 asset** with **20 features**.

Methods

The methods section explains the process and techniques used in this project, in the first part, then explains the data cleaning used to extract and clean the data, in the second part. In the third part of this section we present the data exploration and visualization of the data to gain some insights. The fourth, and last part of this section, we show the modeling approach used in this project.

The process and techniques used

The decision trade system is similar to a **decision support system** (**DSS**) which is an interactive software-based system intended to help decision makers (future contract trader) compile useful information from a combination of raw data, documents, and personal knowledge, or business models to identify and solve problems and make decisions[5]. The future trader decisions could be **buy** the contract, **sell** or not get in a

[2] https://www.b3.com.br/en_us/products-and-services/trading/commodities/product-sheet-8AE490C96D41D3A2016D46017EC97262.htm

[3] "The mean squared error is usually hard to interpret. It's not easy to map an error on returns into the impact on investment decisions. The hit ratio is a more intuitive indicator because it evaluates the proportion of correct guesses (and hence profitable investments). Obviously, it is not perfect: 55% of small gains can be mitigated by 45% of large losses. Nonetheless, it is a popular metric and moreover it corresponds to the usual accuracy measure often computed in binary classification exercises. Here, an accuracy of 0.542 is satisfactory. Even if any number above 50% may seem valuable, it must not be forgotten that transaction costs will curtail benefits. Hence, the benchmark threshold is probably at least at 52%." (Coqueret and Guida 2020)

[4] https://corretora.clear.com.br/plataformas/profit-trader-clear/

[5] https://en.wikipedia.org/wiki/Decision_support_system

position, what is the same to be **neutral** in a asset, this decisions will be our **outcome** $\mathbf{y} = y_t$, which is categorical.

Every trade decision taken, in a future market, occur in a certain time t, in a specific contract and organized marked, for a unique value. For this project the contract is the 4/5 Arabica Coffee Futures traded at B3, which ticker is ICF, and are available for march, may, july, september and december. The ICFFUT is the representative time-series of current contract and some of thus features will be our the dataset. The dimension of the feature matrix X is $T \times K$: where T are daily **observations** and each one of them has K **features**, **inputs**, or **predictors** which will serve as **independent** and **explanatory** variables.

The decision trade system build in this project are made using a similar process and techniques presented at (Coqueret and Guida 2020) and some approaches used by Renaissance Technologies (Zuckerman, 2019).[6] The backtesting protocol propose by (Arnott, Harvey, and Markowitz 2018) are used as reference to evaluate the model.

The process begin with the download, then read the data and create some extensions using the Close price. After the data cleaning we explore the data to gain some insight trough visualization and selected table. This insights is the basis of the modelling approach of this project, that have 3 non linear algorithms: k-Nearest Neighbour Classification, Recursive Partitioning and Regression Trees and Classification and Regression with Random Forest

Data cleaning

For this project we going to use a subset of dataset provided by Profit Trader Clear, and for the sake of **reproducibility**, we will illustrate the concepts based on a single financial dataset available at https://github.com/mrabelosoares/Coffee-Future-Price-Prediction. This dataset comprises information on 1 contract listed at B3, which the time range starts in January 2003 and ends in August 2022. For each point in time, 19 **characteristics** describe the decision in the sample. The dataset are divide between raw data and extensions:

Raw data: Date; Asset; Price (Open, High, Low, Close); Volume; Decision; Open Interest

##Data Clean

#create tempfile and download
dl <- tempfile()
download.file("https://github.com/mrabelosoares/Coffee-Future-Price-Prediction/blob/2044135ec7c5bcfb6f35
#read file XLSX format with decisions
ICFFUT <- read_xlsx("CoffeDatabase.xlsx", sheet = "ICFFUT")
#read file XLSX format with ICF Prices
ICFFUT_XLSX <- read_xlsx("CoffeDatabase.xlsx", sheet = "ICFFUT_XTS")
#Convert XLXS format to Data Frame
DFICFFUT_XTS <- as.data.frame(ICFFUT_XLSX)
#Convert Data Frame to XTS
ICFFUT_XTS <- xts(DFICFFUT_XTS[-1], order.by = as.Date(DFICFFUT_XTS$Date))
```

Extensions: moving average 5 days; moving average 22 days; Bollinger Bands; Rate of Change Oscillator; Relative Strength Index; Stochastic Momentum Index; MACD Oscillator. The description and equations of technical indicator based on price are available at reference manual: https://cran.r-project.org/web/packages/TTR/TTR.pdf

```
##Technical Indicators - Price-Based
#moving average 5 days
Moving_Average_5 <- SMA(ICFFUT_XTS$ICFFUT.Close, n=5)
#moving average 22 days
Moving_Average_22 <- SMA(ICFFUT_XTS$ICFFUT.Close, n=22)
#Bollinger Bands
Bollinger_Bands <- BBands(ICFFUT_XTS$ICFFUT.Close)
#Rate of Change Oscillator
Rate_Change_Oscillator <- ROC(ICFFUT_XTS$ICFFUT.Close, n=10)
#Relative Strength Index
Relative_Strength_Index <- RSI(ICFFUT_XTS$ICFFUT.Close)
#Stochastic Oscillator / Stochastic Momentum Index
Stochastic <- stoch(ICFFUT_XTS$ICFFUT.Close)
#MACD Oscillator
MACD <- MACD(ICFFUT_XTS$ICFFUT.Close)
```

The raw data and the extensions are merged to create the complete data frame.

```
#merge XTS
Full_ICFFUT <- merge(ICFFUT_XTS,
                     Moving_Average_5,
                     Moving_Average_22,
                     Bollinger_Bands,
                     Rate_Change_Oscillator,
                     Relative_Strength_Index,
                     Stochastic,
                     MACD)
#create data frame ICFFUT - 4/5 Arabica Coffee Futures
DFICFFUT <- data.frame(Date=index(Full_ICFFUT), coredata(Full_ICFFUT))
#Merge Data frame ICFFUT - 4/5 Arabica Coffee Futures and ICFFUT
```

```
CDFICFFUT <- left_join(DFICFFUT,
                       ICFFUT |> select(Date, Decision, OpenInterest)) |>
  filter(Date > "2003-02-17") |> #excluding NA
  mutate(Decision  = as.factor(Decision)) #Decision as a factor = Y
```

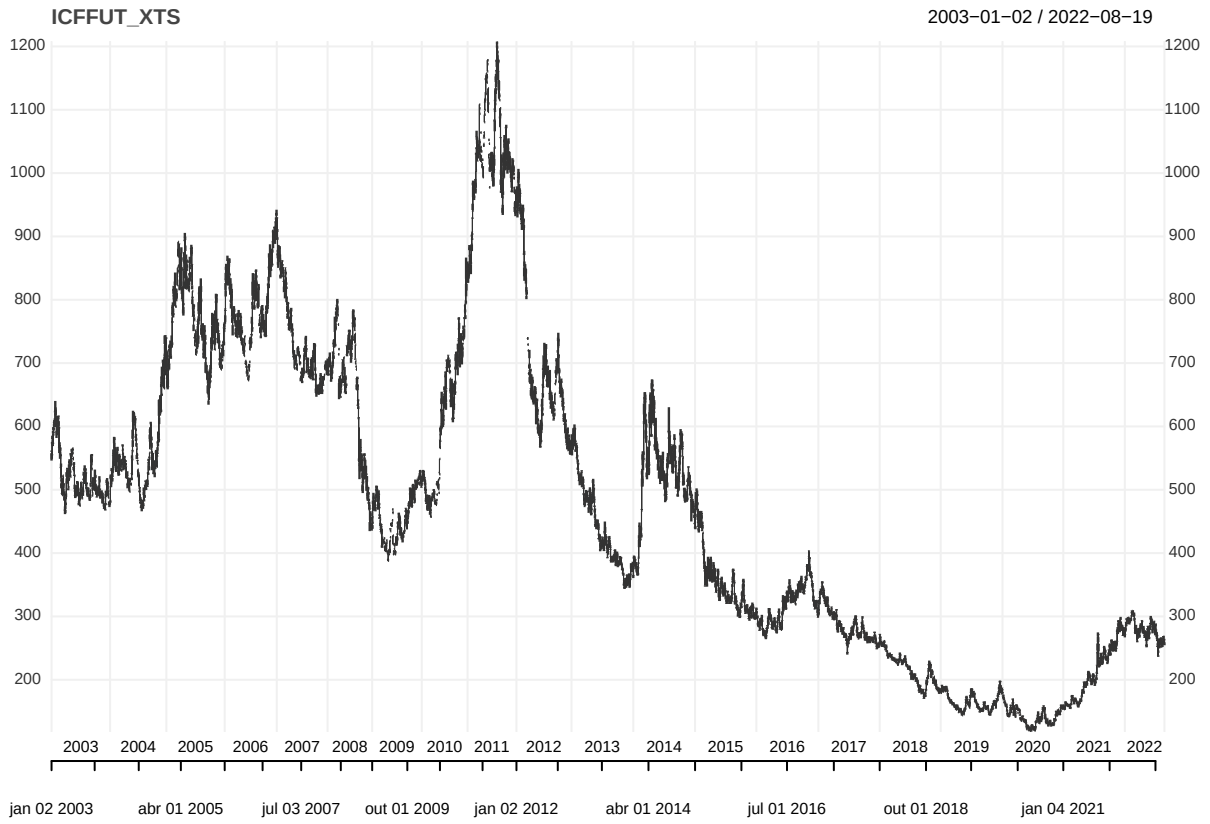
The extensions are technical indicators based on a daily Close Price of ICF and are select based on Chartered Financial Analyst (CFA®) program curriculum. This choice make sense economically since this knowledge are widely disseminated to the market and the decisions are made at the closing call every day.

The decisions was build manually by the author, which look the daily chart and choose the optimal decision every day. As present in the model of chapter 27.8 Case study: is it a 2 or a 7? (Irizarry 2019) the goal of this approach is to look at a picture and classifies what is the best decision at the closing call every day: Buy, Sell, Neutral. Is there a pattern inside the own prices of ICFFUT that bring some prediction?

Data exploration and visualization

The exploration and visualization of the data provide insightful information about the behavior of price trough time. The graphic below show the price range between 2003 and 2022, as we can see the volatility was different for different years.

```
##Data exploration and visualization
#Chart ICFFUT Price
chart_Series(ICFFUT_XTS,type = "candlesticks")
```



A functional trade system implies that every day has at least one trade, in this case the days in which volume are zero we consider a no trade day. As presented below we have 4 days in this condition. For sake of simplicity we going to maintain this days because even without trade the adjust occur.

```
#Day without trade
Notrade <- CDFICFFUT |>
  filter(ICFFUT.Volume == "0") |>
  select(Date, ICFFUT.Close, ICFFUT.Volume, Decision)
Notrade
```

```
##         Date ICFFUT.Close ICFFUT.Volume Decision
## 1 2008-03-06       760.81             0     Sell
## 2 2011-01-25       886.97             0      Buy
## 3 2011-03-07      1046.24             0      Buy
## 4 2011-03-08      1052.12             0      Buy
```

The proprieties of dataset reveal the possibilities and limitations of model approach. Lets check the class, the summary and the structure of data.

```

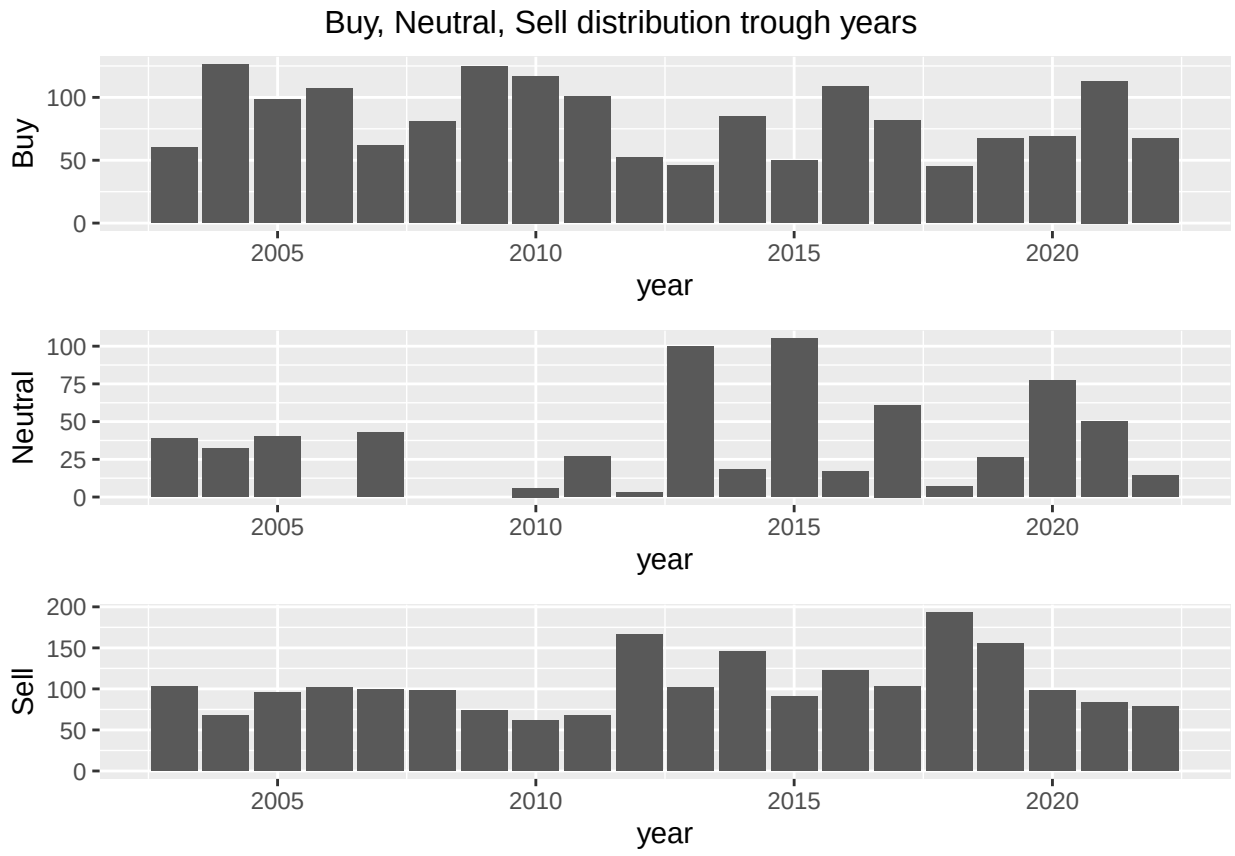
As presented above our matrix have $4,435 \times 21$ variables, mostly numerical column. The close price, the principal column, has 119.6 as minimal value and 1206.0 as maximal, and a median of 470.3. The decision column, our outcome, has a unbalanced prevalence: $Buy = 1662$, $Neutral = 665$, $Sell = 2108$. Lets explore the distribution of decisions trough years.

```
#distribution decision by year
p1 <- CDFICFFUT |>
  mutate(year = year(as.Date(Date)))|>
  filter(Decision == "Buy") |>
  ggplot(aes(x = year)) +
  geom_bar(stat="count") +
  ylab("Buy")

p2 <- CDFICFFUT |>
  mutate(year = year(as.Date(Date)))|>
  filter(Decision == "Neutral") |>
  ggplot(aes(x = year)) +
  geom_bar(stat="count") +
  ylab("Neutral")

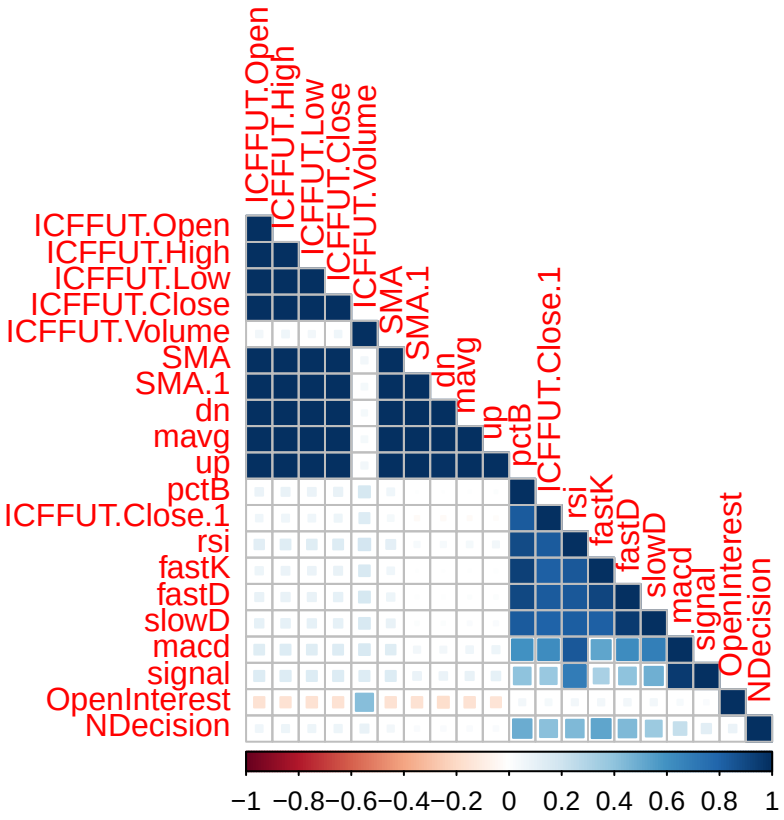
p3 <- CDFICFFUT |>
  mutate(year = year(as.Date(Date)))|>
  filter(Decision == "Sell") |>
  ggplot(aes(x = year)) +
  geom_bar(stat="count") +
  ylab("Sell")

#Buy, Neutral, Sell distribution trough years
gridExtra::grid.arrange(p1, p2, p3,
                        nrow = 3,
                        top = "Buy, Neutral, Sell distribution trough years")
```



The graphs show different prevalence for different years, this a relevant information for building a general model, since the prevalence affect the precision and recall of model, and consequently the measurement of performance. The correlation between variables and outcome could bring more information about the behavior of data, which reflects the decisions of traders. To transform the decision from a factor to a number we replace *Neutral* by 0, *Buy* for 1, and *Sell* for -1.

```
#correlation between variables and outcome
NDFICFFUT <- CDFICFFUT |> mutate( #Decision as a number
  NDecision = case_when(
    Decision == "Neutral" ~ 0, #If Neutral, then 0
    Decision == "Buy" ~ 1,#If Buy, then 1
    Decision == "Sell" ~ -1)#If sell, then -1
  ) |> select(-Decision, -Date) #less categorical and date column
C <- cor(NDFICFFUT) #correlation matrix
corrplot(C, method = 'square', type = 'lower')
```



The outcome are high correlated with extension fastK, which is 1 of 3 components of Stochastic Momentum Index. On the other side, the prices, the moving averages and the Bollinger Bands are low correlated with decisions. The volume has some correlations with Open interest, but almost nothing with others variables.

The result of decisions made trough years, or the sum of profits, could be calculated using the code below. Considering the decision made at every day close call the potential return are the difference between today close price less the yesterday close price. Another important feature in this model is the status of daily position, which could be hold or change, either *Neutral*,*Buy* or *Sell*.

The combination of status and current, or lag decision, determine the multiplier we use to calculate the adjust we going to receive or pay. Lets show a example to illustrate the idea, my decision last trade day was to be *Neutral*, and today is *Buy*, which means a change, the multiplier will be 0, because we have no adjust to pay or receive this day. In the next day we hold the *Buy* position, then or multiplier will be 1 and we receive the positive change in price or we pay the negative difference in price. To complete the model we measure the sum of profit, daily adjust payed or received, for the last 22 days, which is a proxy of the monthly profit.

```
#empirical optimal results - sum last 22 days
profitICFFUT <- CDFICFFUT |>
  arrange(Date) |>
  mutate(return = ICFFUT.Close - lag(ICFFUT.Close) ,
         status = as.factor(case_when(
           Decision == lag(Decision) ~ "Hold",
           Decision != lag(Decision) ~ "Change")),
         multiplier = case_when(
           status == "Change" & lag(Decision) == "Neutral" ~ 0,
           status == "Hold" & Decision == "Neutral" ~ 0,
```

```
          status == "Change" & lag(Decision) == "Buy" ~ 1,
          status == "Hold" & Decision == "Buy" ~ 1,
          status == "Change" & lag(Decision) == "Sell" ~ -1,
          status == "Hold" & Decision == "Sell" ~ -1),
        adjust = return * multiplier,
        profit = case_when(
          Decision == "Neutral" ~ 0,
          Decision != "Neutral" ~ sum_run(adjust, k=22)
          ))
summary(profitICFFUT |> select(return, status, adjust, profit))
```

```
##      return             status         adjust            profit

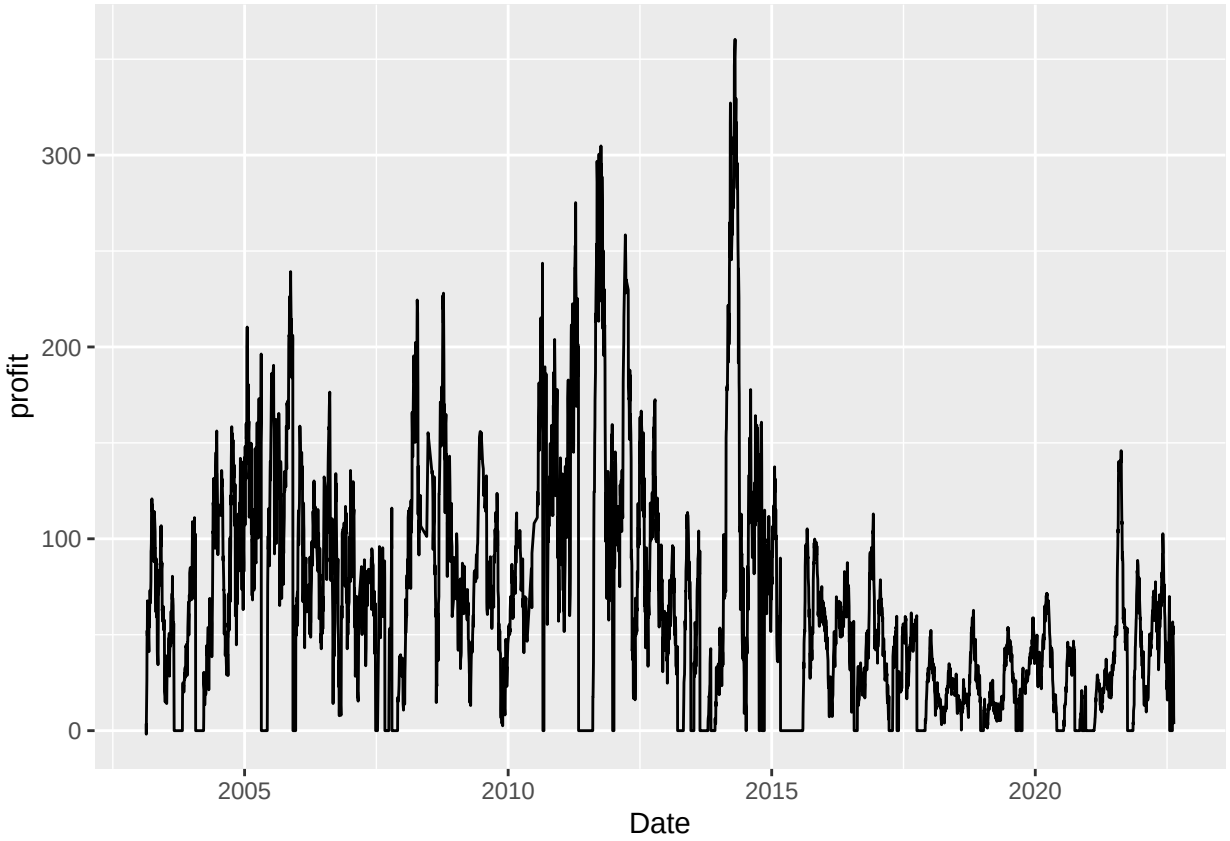
```

The daily change, return, show the volatility of the asset, which reached 71.42 in one day, and has a median and mean below zero, which is compatible with the theory that the future price converge to spot price, or the tendency to lost value trough time. The status was changed in 245 periods, or 5,5% of the days, this a important feature of the model that intended to minimize the trade cost. The profit, the ultimate goal of decision trade system, are consistently above zero and has median of 51.70 for the last 22 days. The annual profit could be verified in the table below, and show this median are too high for the last 5 years.

```
#profit adjust from the last 22 days
profitICFFUT |>
  ggplot(aes(Date, profit)) +
  geom_line()
```



```
#profit by year
profitY <- profitICFFUT |> mutate(Year = as.factor(year(as.Date(Date))))
profit_table <- as.data.frame(tapply(profitY$adjust,
                                     profitY$Year,
                                     FUN=sum,
                                     na.rm = TRUE))
colnames(profit_table) <- "profit_year"

Modeling approach

The decision trade system is better as its errors has decrease, for this project the error has a categorical metrics evaluation. The summary metrics for this project is the F1-score, or balanced accuracy, that is the harmonic average of precision recall. As presented in 27.4.5 Balanced accuracy and F1 score (Irizarry 2019) "The $F1$ -score can be adapted to weigh specificity and sensitivity differently. To do this, we define β to represent how much more important sensitivity is compared to specificity and consider a weighted harmonic average". For this project the $\beta = 1$, because the sensitivity has the same importance of specificity:

$$F1 = \frac{1}{\frac{\beta^2}{1+\beta^2}\frac{1}{\text{recall}} + \frac{1}{1+\beta^2}\frac{1}{\text{precision}}}$$

For this project the $F1 > 0.50$ is the goal. The value was taken from (Coqueret and Guida 2020) where any accuracy above 50% may seem valuable.

Machine Learning

"If we have enough data, I know we can make predictions," Simons told a colleague.[7]

The machine learning decisions are based on algorithms build with data, so for this project the dataset CDFICFFUT are going to be used to train and test the model. The training_sample and testing_sample are build by slicing the time, where the sample before 2020 are the training set and after the test set. The proportion of data for testing is 17% of total, in line with typical choice of 10%-20%(Irizarry 2019):

```
#Modeling approach
#create a partition
separation_date <- as.Date("2020-01-02")
training_sample <- filter(CDFICFFUT, Date < separation_date)
testing_sample <- filter(CDFICFFUT, Date >= separation_date)
```

k-Nearest Neighbor Classification approach

The first model in this project is the k-nearest neighbors (kNN) approach, used by Renaissance Technologies and presented at chapter 29.1 Motivation with k-nearest neighbors (Irizarry 2019). The multiple dimensions adaptability is a important feature, specialy in finance, to estimate $p(x_1, x_2)$:

$$p(x_1, x_2) = \Pr(Y = 1 \mid X_1 = x_1, X_2 = x_2).$$

As presented "for any point $(x1, x2)$ for which we want an estimate of $p(x1, x2)$, we look for the k nearest points to $(x1, x2)$ and then take an average of the 0s and 1s associated with these points. We refer to the set of points used to compute the average as the *neighborhood*." (Irizarry 2019). We going to use the knn3 function of caret package, with a $k = 5$, to train the dataset. Then we show the first 5 rows of model by probability and class of decision.

[7] Zuckerman, Gregory. The Man Who Solved the Market (p. 2). Penguin Publishing Group. Kindle edition

```r
#defining the predictors - Model 1
knn_fit <- knn3(Decision ~ .,
                data = training_sample, k=5)
knn_fit
```

```
## 5-nearest neighbor model
## Training set outcome distribution:
##
##     Buy Neutral    Sell
##    1413     524    1847
```

```r
#probability and class of model
head(predict(knn_fit, testing_sample, type = "prob"))
```

```
##      Buy Neutral Sell
## [1,] 0.6       0  0.4
## [2,] 0.0       0  1.0
## [3,] 0.6       0  0.4
## [4,] 0.6       0  0.4
## [5,] 0.6       0  0.4
## [6,] 0.4       0  0.6
```

```r
head(predict(knn_fit, testing_sample, type = "class"))
```

```
## [1] Buy  Sell Buy  Buy  Buy  Sell
## Levels: Buy Neutral Sell
```

```r
#balanced accuracy - model 1
y_hat_knn <- predict(knn_fit, testing_sample, type = "class")
confusionMatrix(y_hat_knn, testing_sample$Decision)$overall["Accuracy"]
```

```
##  Accuracy
## 0.4285714
```

```r
cm1 <- confusionMatrix(y_hat_knn, testing_sample$Decision)
cm1[["byClass"]][ , "Precision"]
```

```
##     Class: Buy Class: Neutral    Class: Sell
##      0.4654545             NA      0.4015957
```

```r
cm1[["byClass"]][ , "Recall"]
```

```
##     Class: Buy Class: Neutral    Class: Sell
##      0.5140562      0.0000000      0.5785441
```

```r
KNN <- cm1[["byClass"]][ , "F1"]
```

The accuracy of 0.4285714 is better than guessing, which is 0.3333, but is below or goal of 0.5. The F1 - score is below 0.5 for Buy and Sell decisions, and is zero for be Neutral. This could be a consequence of low prevalence of Neutral, or undetected pattern related with this decision.

Recursive Partitioning for classification trees approach

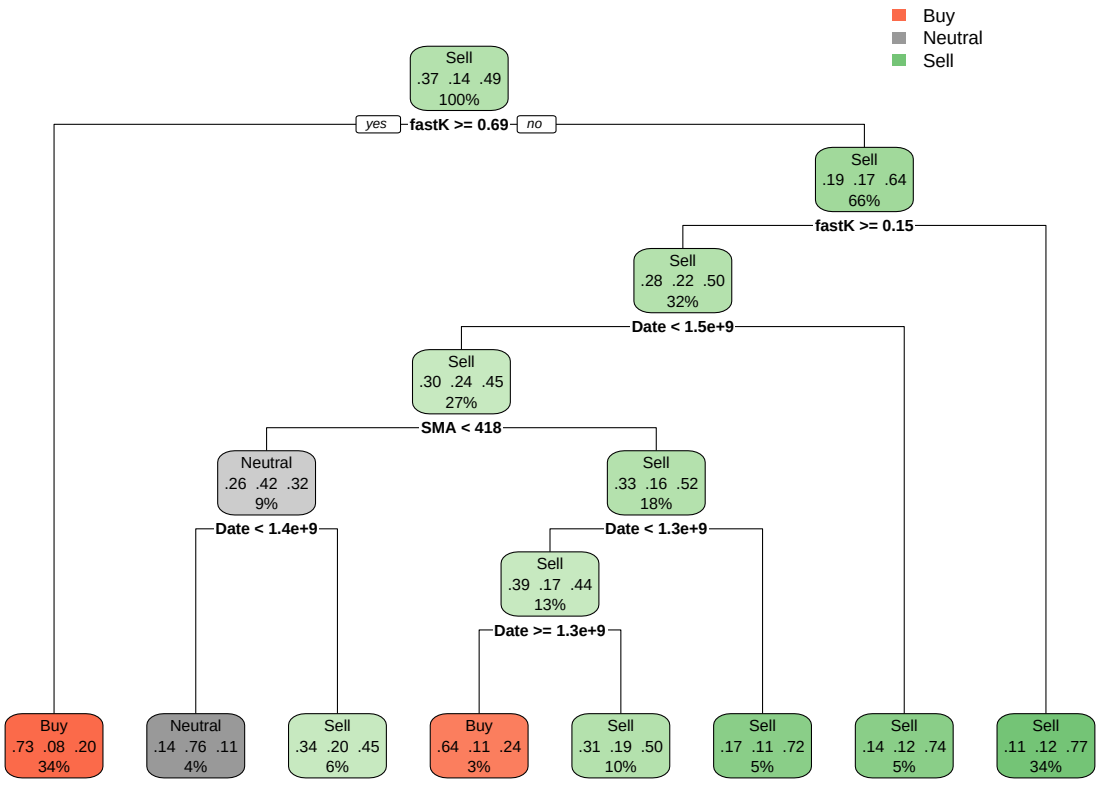
The tree based method, presented in chapter 6 (Coqueret and Guida 2020), is our second model, and was chosen because has efficient forecast, are easy to visualize and could model human decision. The goal of classification tree is to split the dataset into homogeneous cluster, by minimizing dispersion inside each cluster. The output present the proportion of each class, in each cluster, in this case for J classes, we denote these proportions with p_j, and for each cluster k, the usual loss functions are:

$$\text{Gini}(j) = 1 - \sum_{j=1}^{J} p_j^2;$$

$$\text{entropy}(j) = -\sum_{k=1}^{K} \hat{p}_{j,k} \log(\hat{p}_{j,k}), \text{ with } 0 \times \log(0) \text{ defined as } 0$$

The first split is the most important of the model because show the most general rule of data aggregation and reveal the most relevant step to taken in trade decision. To implement this classification tree we going to use rpart function in the rpart package, with default complexity parameter.

```
#defining the predictors - Model 2
fit <- rpart(Decision ~ ., data = training_sample)
rpart.plot(fit)
```



```
#Structural break

##     Class: Buy Class: Neutral    Class: Sell
##      0.5476190             NA      0.4987469
```

```
cm2[["byClass"]][ , "Recall"]
```

```
##     Class: Buy Class: Neutral    Class: Sell
##      0.5542169      0.0000000      0.7624521
```

```
Classification_Tree <- cm2[["byClass"]][ , "F1"]
```

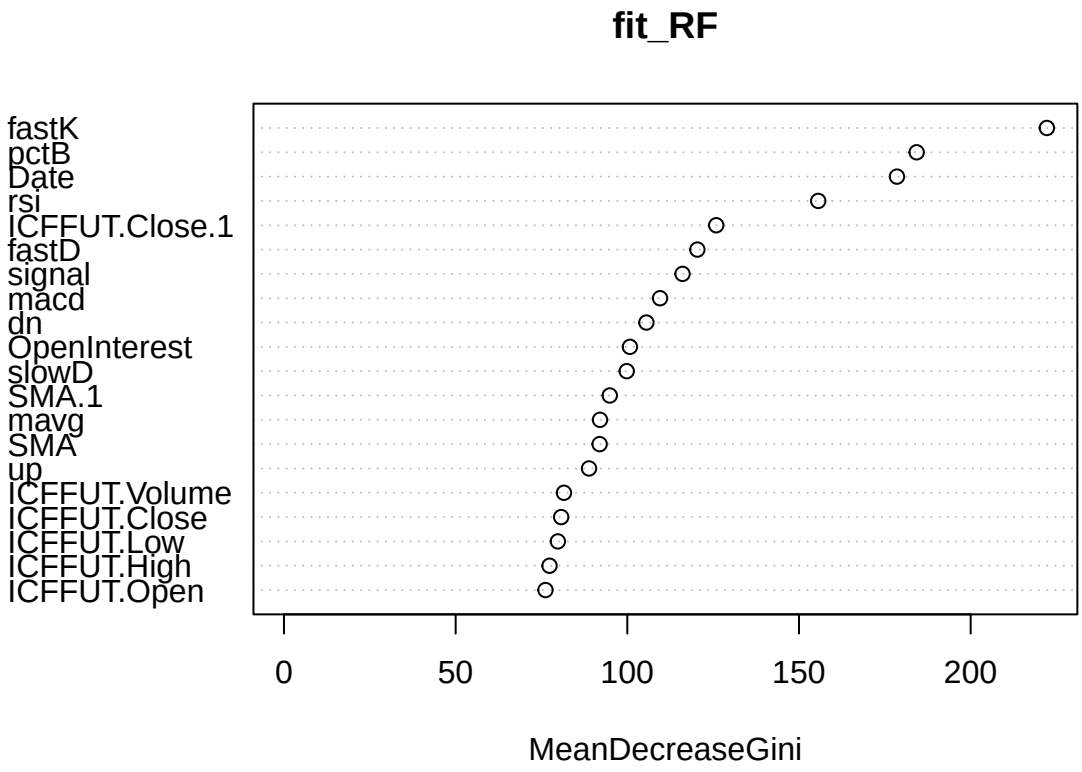
The general rule of trade decision in ICFFUT is to be $Selled$, but if the fastK is bigger than 0.69 the best decision is to change the decision to *Buy*. The *Buy* has a proportion of 34% of decisions and has a 73% of probability of being right in this decision, this correspond to a F1-score of 0.55. The *Sell* decision and *Neutral* decision has structural breaks[8], which means that decisions change throughout time. The *Sell* decision has a F1-score of 0.60, much higher than our goal, but the *Neutral* decision has no F1-score. This reveal the limitations of this approach, since the prevalence differ by class and by year, or could indicate the necessity to review the parameters.

Classification and Regression with Random Forest approach

A Random Forest is the last approach to solve the trade decision system problem presented in this project. The goal of this approach is to take the averaging of multiples simple trees to reduce the instability and improve the prediction performance, and the algorithm do this by bootstrapping the sample to induce randomness. The Random Forest used in this project follow the default setup, but the algorithm has more than 27 arguments and has 17 components values, which provides a wide range of tuning possibilities.

[8] https://en.wikipedia.org/wiki/Structural_break

```r
#defining the predictors - Model 3
fit_RF <- randomForest(Decision ~., data = training_sample)
#Variable Importance Plot
varImpPlot(fit_RF)
```



```r
#accuracy - model 3
y_hat_RF <- predict(fit_RF, testing_sample, type = "class")
confusionMatrix(y_hat_RF, testing_sample$Decision)$overall["Accuracy"]
```

```
##  Accuracy
## 0.4715822
```

```r
cm3 <- confusionMatrix(y_hat_RF, testing_sample$Decision)
cm3[["byClass"]][ , "Precision"]
```

```
##     Class: Buy Class: Neutral    Class: Sell
##      0.4161290      0.2500000      0.5285285
```

```r
cm3[["byClass"]][ , "Recall"]
```

```
##     Class: Buy Class: Neutral    Class: Sell
##      0.5180723      0.0141844      0.6743295
```

```
Random_Forest <- cm3[["byClass"]][ , "F1"]
```

The model reveal that the most important variable is the fastK, folowed by pctB, which is a component of Bollinger Bands indicator and quantifies the price relative to the upper and lower Bollinger Band. The Date is a important variable too, showing that model most to adapt to different time frame. The F1 score of *Neutral* decision is 0.013, which is very low, but it´s not null, showing some improvement regarding the two models before. The *Sell* decision has a F1 score of 0.58, above our goal, but smaller than the model of tree classification. The improvement in *Neutral* decision come with a cost to *Buy* decision that has a F1 score of 0.45 for this model, below our goal.

Results

```
#Results
knitr::kable(tibble(c("Buy", "Neutral", "Sell"),
                    KNN,
                    Classification_Tree,
                    Random_Forest))
```

c(”Buy”, ”Neutral”, ”Sell”)	KNN	Classification_Tree	Random_Forest
Buy	0.4885496	0.5508982	0.4615385
Neutral	NA	NA	0.0268456
Sell	0.4740973	0.6030303	0.5925926

Conclusion

The recommendation system, developed in this project, provide suggestions for items that are most pertinent to a particular user. The goal of this project was achieved and the $RMSE$ of matrix factorization of 0.78 is lower than our target 0.86490. A larger dataset could provide a even better model since we have more data to train, and is one of the limitations of this project. The addition of more variables could be a good outlook for future works since can capture more structures and latent factors in the data.

Evaluation metrics

Avoiding False Positives: A Protocol

Model that makes sense economically: Renaissance Technologies Trading Strategies

1- Mean Reversion Strategy: Buy if the close price move a certain level below their recent trend line, Sell if above certain level above and be Neutral if the price is too close of trend line.

2- Stochastic Strategy: Non linear machine learning Kernel

3- The Kelly Criterion: scientific gambling method Assumption: future returns depend on decisions toked on close price. The relationship between the characteristics of market and performance is largely unknown and probably time-varying. This is why ML can be useful: to detect some hidden patterns beyond the documented asset pricing anomalies. Moreover, dynamic training allows to adapt to changing market conditions.

1. Research Motivation: ex ante/ex post economic foundation
a) Does the model have a solid economic foundation?

Coffee It is one of the most important commodities traded globally and one of the most popular beverages in the world. World production is spread over 55 developing countries and is conducted by about 26 million producers, cultivated in tropical and subtropical areas.

The development of local organizations or instruments to help managing price risk, such as organized futures, in developing countries, like Brazil, is a important step to minimize the risk and challenges of small producers, since the larger and more liquids futures markets are located in the United States and Europe.

The Futures price volatility is large once coffee market has low price elasticity of demand and supply in the short run. In addition, previous studies have pointed to the existence of asymmetric price transmission within the coffee chain. Because of the concentration of roasting and retail sectors, retail prices respond faster to price increases than to price decreases, while farm prices follow more closely supply and demand conditions.

b) Did the economic foundation or hypothesis exist before the research was conducted?
Price changes are commonly caused by the arrival of new information from ICO crop reports, as presented in work The Reaction of Coffee Futures Price Volatility to Crop Reports (2017)

2. Multiple Testing and Statistical Methods
a) Did the researcher keep track of all models and variables that were tried (both successful and unsuccessful) and are the researchers aware of the multiple-testing issue?

b) Is there a full accounting of all possible interaction variables if interaction variables are used?

c) Did the researchers investigate all variables set out in the research agenda or did they cut the research as soon as they found a good model?

3. Data and Sample Choice
a) Do the data chosen for examination make sense? And, if other data are available, does it make sense to exclude these data?
b) Did the researchers take steps to ensure the integrity of the data?
c) Do the data transformations, such as scaling, make sense? Were they selected in advance? And are the results robust to minor changes in these transformations?
d) If outliers are excluded, are the exclusion rules reasonable?
e) If the data are winsorized, was there a good reason to do it? Was the winsorization rule chosen before the research was started? Was only one winsorization rule tried (as opposed to many)?

4. Cross-Validation
a) Are the researchers aware that true out-of-sample tests are only possible in live trading?
b) Are steps in place to eliminate the risk of out-of-sample "iterations" (i.e., an in-sample model that is later modified to fit out-of-sample data)?
c) Is the out-of-sample analysis representative of live trading? For example, are trading costs and data revisions taken into account?

5. Model Dynamics
a) Is the model resilient to structural change and have the researchers taken steps to minimize the overfitting of the model dynamics?
b) Does the analysis take into account the risk/likelihood of overcrowding in live trading?
c) Do researchers take steps to minimize the tweaking of a live model?

6. Complexity
a) Does the model avoid the curse of dimensionality?
b) Have the researchers taken steps to produce the simplest practicable model specification?
c) Is an attempt made to interpret the predictions of the machine learning model rather than using it as a black box?

7. Research Culture
a) Does the research culture reward quality of the science rather than finding the winning strategy?
b) Do the researchers and management understand that most tests will fail?
c) Are expectations clear (that researchers should seek the truth not just something that works) when research is delegated?

Category #1: Research Motivation

Category #2: Multiple Testing and Statistical Methods Keep track of: what is tried, combinations of variables, Beware the parallel universe problem.

Category #3: Sample Choice and Data Define the test sample ex ante. Ensure data quality Document choices in data transformations Do not arbitrarily exclude outliers. Select Winsorization level before constructing the model.

Category #4: Cross-Validation Acknowledge out of sample is not really out of sample Understand iterated out of sample is not out of sample. Do not ignore trading costs and fees.

Category #5: Model Dynamics Be aware of structural changes. Acknowledge the Heisenberg Uncertainty Principle and overcrowding. Refrain from tweaking the model.

Category #6: Model Complexity Beware the curse of dimensionality. Pursue simplicity and regularization. Seek interpretable machine learning.

Category #7: Research Culture Establish a research culture that rewards quality. Be careful with delegated research
